【論文の内容の要約】

Two field experiments were conducted to assess nitrous oxide (N\textsubscript{2}O) emissions in response to different nitrogen fertilizer types and amounts in heavily fertilized tea fields in Japan.

The first experiment was conducted in Fuchu, Japan. Four treatments were implemented: CONT: no fertilizer, CONV: conventional fertilization, ½CONV, and CHEM: chemical fertilization. Gas samples were collected 5–8 times after every fertilizer application using the closed chamber method. The results revealed high seasonal variation in N\textsubscript{2}O emissions driven by soil temperature rather than the fertilizer application time. The soil temperature at a depth of 0–10 cm was significantly correlated with N\textsubscript{2}O emission (P<0.01). The highest cumulative N\textsubscript{2}O emission (73.2 kg N ha\textsuperscript{-1} yr\textsuperscript{-1}) was observed in the CHEM treatment, followed by the CONV treatment (65.0 kg N ha\textsuperscript{-1} yr\textsuperscript{-1}), the ½CONV treatment (18.6 kg N ha\textsuperscript{-1} yr\textsuperscript{-1}) and the CONT treatment (1.8 kg N ha\textsuperscript{-1} yr\textsuperscript{-1}). The highest N\textsubscript{2}O emission factor (7.9%) was found in the CHEM treatment, followed by the CONV treatment (7.0%) and the ½CONV treatment (3.7%). There were spatial differences in the soil characteristics across the tea field. Accurate estimates of the ratios of N\textsubscript{2}O emitted from the four treatments during the two crop seasons were 47.9% and 52.1% from the soil on the rows (108.6 kg N ha\textsuperscript{-1}) and under the canopies (118.3 kg N ha\textsuperscript{-1}), respectively.

The second field experiment was conducted for 2 years in Green Tea Laboratory of Saitama Prefectural Agriculture and Forestry Research Center, Iruma, Saitama, Japan from March 2014 to December 2015. Controlled release fertilizer (CRF) or organic fertilizer (ORG) was applied with the amount of 450 kg N ha\textsuperscript{-1} yr\textsuperscript{-1} in 2014 and 397 kg N ha\textsuperscript{-1} yr\textsuperscript{-1} in 2015.

The results showed, under the same amount of fertilizer application, cumulative N\textsubscript{2}O emission was lowest in CRF in the second experiment followed by ORG treatment of the second experiment and the highest value was found in ½CONV treatment of the first experiment. Yield, quality and flavor of tea leaves were not affected by different types of nitrogen fertilizer significantly, however, CRF showed relatively higher values than those of other 2 treatments.
